Getting Started with Arduino

Introduction: What Arduino is and why you'd want to use it.

Installation: Step-by-step instructions for setting up the Arduino software and connecting it to an Arduino Uno, Mega2560, Duemilanove, Mega, or Diecimila.

- + [Windows](#)
- + [Mac OS X](#)
- + [Linux](#) (on the playground wiki)

Environment: Description of the Arduino development environment and how to change the default language.

Libraries: Using and installing Arduino libraries.

Troubleshooting: Advice on what to do if things don't work.

Breadboard

Values

- **Examples** : 9, 10, 'c', "Alan", True, False
- **Types**: Whole Number, Text, Bits
- **Operations**: 9+10, 'c' in "Alan", test=!test

Steps

- Store a value

```
int led = 13;
```

- Turn on an LED

```
digitalWrite(led, HIGH);
```

- Wait for 1000 milliseconds

```
delay(1000);
```

LEDs - Light Emitting Diodes

Simple LED

MIHIGH > BlinkSimple

Get your LED to blink either Red, Green or Blue

Attach your circuit and upload the program

Pinmapping shows which row is Digital Pin 13, plug the Red, Green or Blue wire there

Plug the yellow wire into ground

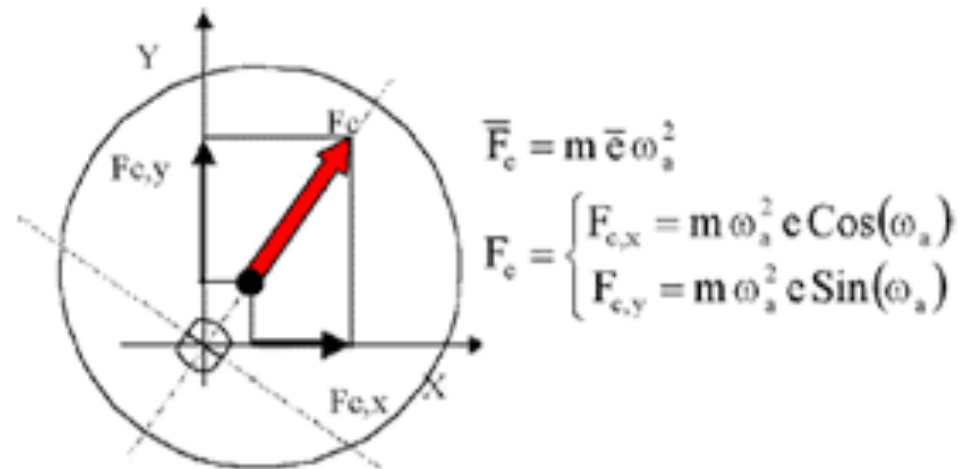

Vibration Motor

Structure of motor

Example of eccentric mass adopted on moto vibrator

Names

Named, stored values are called *Variables*

MIHIGH > BlinkNamed

Upload to board

Connect a different output between Digital Pin 13 and Ground

RGB LED

RGB Color control

Figure out the wiring using the Pinmapping and reading the code

Reference Material

Light Emitting Diode
(LED for short)

LEDs are diodes, so they only allow current to pass in one direction. The longer leg should be positive, the shorter one negative. Round LEDs are also flat near the negative leg. They generate lots of different frequencies or colors of light. Only some of them are visible. Many components contain three LEDs; Red, Green and Blue (RGB for short) blending them to create the impression of any colour since the human eye can only sense these three colors.

Resistors limit the movement of charge

Resistors connect different parts of circuits like a wire. They allow charge to move as part of a circuit's behaviour. However, they have different *resistances* to the movement of charge, measured in Ohms (using the symbol Ω). Circuit designer can therefore control how fast charge moves. If you imagine charge is like water, a resistor is like a narrow pipe. Pressure (voltage) can still build up, but not much water can get through.

Capacitors store a little bit of charge

Capacitors have the ability to store a small amount of charge. Storage is measured in Farads (using the symbol F). In many circuits they help to smooth out unwanted variations in energised charge by releasing it when there's a dip, and absorbing it when there's a peak.

Microcontroller combines a computer with inputs and outputs

The Arduino Uno and @ShrimpingIt boards both use the ATMEGA328 family of microcontrollers. They can be programmed again and again by sending new digital behaviours over the serial pins (yellow and orange) using the USB device below. Programs can easily sense or act on the physical world by controlling or measuring the voltage of different pins.

USB Serial Receiver and Transmitter

Our example circuit uses a CP2102 USB to UART adaptor, which a laptop or desktop can use send and receive information to the Microcontroller. When programming, the digital behaviour, or program, is sent using this device. For some applications, you may also use this to communicate with a desktop or laptop whilst the project circuit is running.
